

Normalization By Evaluation of Types in $R\omega\mu$

ALEX HUBERS, The University of Iowa, USA

Abstract

We describe the normalization-by-evaluation (NbE) of types in $R\omega\mu$, a row calculus with recursive types, qualified types, and a novel *row complement* operator. Types are normalized to $\beta\eta$ -long forms modulo a type equivalence relation. Because the type system of $R\omega\mu$ is a strict extension of System $F\omega\mu$, much of the type reduction is isomorphic to reduction of terms in the STLC. Novel to this report are the reductions of row, record, and variant types.

1 The $R\omega\mu$ calculus

For reference, Figure 1 describes the syntax of kinds, predicates, and types in $R\omega\mu$. We forego further description to the next section.

Type variables $\alpha \in \mathcal{A}$ Labels $\ell \in \mathcal{L}$

Kinds $\kappa ::= \star \mid L \mid R^K \mid \kappa \rightarrow \kappa$
Predicates $\pi, \psi ::= \rho \lesssim \rho \mid \rho \odot \rho \sim \rho$
Types $\mathcal{T} \ni \phi, \tau, v, \rho, \xi ::= \alpha \mid \pi \Rightarrow \tau \mid \forall \alpha : \kappa. \tau \mid \lambda \alpha : \kappa. \tau \mid \tau \tau$
 $\mid \{\xi_i \triangleright \tau_i\}_{i \in 0 \dots m} \mid \ell \mid \# \tau \mid \phi \$ \rho \mid \rho \setminus \rho$
 $\mid \tau \rightarrow \tau \mid \Pi \mid \Sigma \mid \mu \phi$

Fig. 1. Syntax

1.1 Example types

Wand's problem and a record modifier:

wand : $\forall l \ x \ y \ z \ t. \ x \odot y \sim z, \ \{l \triangleright t\} \lesssim z \Rightarrow \#l \rightarrow \Pi x \rightarrow \Pi y \rightarrow t$
modify : $\forall l \ t \ u \ y \ z1 \ z2. \ \{l \triangleright t\} \odot y \sim z1, \ \{l \triangleright u\} \odot y \sim z2 \Rightarrow$
 $\#l \rightarrow (t \rightarrow u) \rightarrow \Pi z1 \rightarrow \Pi z2$

"Deriving" functor typeclass instances:

type Functor : $(\star \rightarrow \star) \rightarrow \star$
type Functor = $\lambda f. \forall a \ b. (a \rightarrow b) \rightarrow f \ a \rightarrow f \ b$

fmapS : $\forall z : R[\star \rightarrow \star]. \Pi (\text{Functor } z) \rightarrow \text{Functor } (\Sigma z)$
fmapP : $\forall z : R[\star \rightarrow \star]. \Pi (\text{Functor } z) \rightarrow \text{Functor } (\Pi z)$

And a desugaring of booleans to Church encodings:

desugar : $\forall y. \text{BoolF} \lesssim y, \ \text{LamF} \lesssim y \setminus \text{BoolF} \Rightarrow$
 $\Pi (\text{Functor } (y \setminus \text{BoolF})) \rightarrow \mu (\Sigma y) \rightarrow \mu (\Sigma (y \setminus \text{BoolF}))$

2 Mechanized syntax

2.1 Kind syntax

Our formalization of $R\omega\mu$ types is *intrinsic*, meaning we define the syntax of *typing* and *kinding judgments*, foregoing any formalization of or indexing-by untyped syntax. The only "untyped" syntax is that of kinds, which are well-formed grammatically. We give the syntax of kinds and kinding environments below.

```

data Kind : Set where
  ★      : Kind
  L      : Kind
  _'→_   : Kind → Kind → Kind
  R[ ]   : Kind → Kind

data KEnv : Set where
  ∅      : KEnv
  _„_    : KEnv → Kind → KEnv

```

The kind system of $R\omega\mu$ defines \star as the type of types; L as the type of labels; (\rightarrow) as the type of type operators; and $R[\kappa]$ as the type of rows containing types at kind κ . Kinding environments are isomorphic to lists of kinds.

The syntax of intrinsically well-scoped De-Brujin type variables is given below. Type variables indexed in this way are analogous to the $_ \in _$ relation for Agda lists—that is, each type variable is itself a proof of its location within the kinding environment. Let the metavariables Δ and κ range over kinding environments and kinds, respectively.

```

data TVar : KEnv → Kind → Set where
  Z : TVar (Δ „ κ) κ
  S : TVar Δ κ1 → TVar (Δ „ κ2) κ1

```

2.1.1 Partitioning kinds. It will be necessary to partition kinds by two predicates. The predicate `NotLabel κ` is satisfied if κ is neither of label kind, a row of label kind, nor a type operator that returns a labeled kind. It is trivial to show that this predicate is decidable.

```

NotLabel : Kind → Set
NotLabel ★ = ⊤
NotLabel L = ⊥
NotLabel (κ1 '→ κ2) = NotLabel κ2
NotLabel R[ κ ] = NotLabel κ

notLabel? : ∀ κ → Dec (NotLabel κ)
notLabel? ★ = yes tt
notLabel? L = no λ ()
notLabel? (κ '→ κ1) = notLabel? κ1
notLabel? R[ κ ] = notLabel? κ

```

The predicate `Ground κ` is satisfied when κ is the kind of types or labels, and is necessary to reserve the promotion of neutral types to just those at these kinds. It is again trivial to show that this predicate is decidable, and so a definition of `ground?` is omitted.

```

Ground : Kind → Set
ground? : ∀ κ → Dec (Ground κ)
Ground ★ = ⊤
Ground L = ⊤
Ground (κ '→ κ1) = ⊥
Ground R[ κ ] = ⊥

```

2.2 Type syntax

We represent the judgment $\Gamma \vdash \tau : \kappa$ intrinsically as the data type $\text{Type } \Delta \kappa$. The data type $\text{Pred } \text{Type } \Delta \text{R}[\kappa]$ represents well-kinded predicates indexed by $\text{Type } \Delta \kappa$. The two are necessarily mutually inductive. Note that the syntax of predicates will be the same for both types and normalized types, and so the Pred data type is indexed abstractly by type Ty .

```
data Pred (Ty : KEnv → Kind → Set) Δ : Kind → Set
data Type Δ : Kind → Set
```

We must also define syntax for *simple rows*, that is, row literals. For uniformity of kind indexing, we define a SimpleRow by pattern matching on the syntax of kinds. Like with Pred , simple rows are indexed by abstract type Ty so that we may reuse the same pattern for normalized types.

```
SimpleRow : (Ty : KEnv → Kind → Set) → KEnv → Kind → Set
SimpleRow Ty Δ R[κ] = List (Label × Ty Δ κ)
SimpleRow _ _ _ = ⊥
```

A simple row is *ordered* if it is of length ≤ 1 or its corresponding labels are ordered according to some total order $<$. We will restrict the formation of row literals to just those that are ordered, which has two key consequences: first, it guarantees a normal form (later) for simple rows, and second, it enforces that labels be unique in each row. It is easy to show that the Ordered predicate is decidable.

```
Ordered : SimpleRow Type Δ R[κ] → Set
ordered? : ∀ (xs : SimpleRow Type Δ R[κ]) → Dec (Ordered xs)
Ordered [] = ⊤
Ordered (x :: []) = ⊤
Ordered ((l1, _) :: (l2, τ) :: xs) = l1 < l2 × Ordered ((l2, τ) :: xs)
```

The syntax of well-kinded predicates is exactly as expected.

```
data Pred Ty Δ where
  _·~_ : (ρ1 ρ2 ρ3 : Ty Δ R[κ]) → Pred Ty Δ R[κ]
  _≤_ : (ρ1 ρ2 : Ty Δ R[κ]) → Pred Ty Δ R[κ]
```

The syntax of kinding judgments is given below. The formation rules for λ -abstractions, applications, arrow types, and \forall and μ types are standard and omitted. The constructor $_ \Rightarrow _$ forms a qualified type given a well-kinded predicate π and a \star -kinded body τ . Labels are formed from label literals and cast to kind \star via the $_ _$ constructor. The remaining constructors describe row formation: The constructor $_ _$ forms a row literal from a well-ordered simple row. We additionally allow the syntax $_ \triangleright _$ for constructing row singletons of (perhaps) variable label; this role can be performed by $_ _$ when the label is a literal. The $_ _ _$ constructor describes the map of a type operator over a row. Π and Σ form records and variants from rows for which the NotLabel predicate is satisfied. Finally, the $_ \setminus _$ constructor forms the relative complement of two rows. The novelty in this report will come from showing how types of these forms reduce.

```
data Type Δ where
  ' : (α : TVar Δ κ) → Type Δ κ
  _⇒_ : (π : Pred Type Δ R[κ1]) → (τ : Type Δ ★) → Type Δ ★
  lab : (l : Label) → Type Δ L
```

```

148  [ ] : (τ : Type Δ L) → Type Δ ★
149  (|_) : (xs : SimpleRow Type Δ R[ κ ]) (ordered : True (ordered? xs)) → Type Δ R[ κ ]
150  _>_ : (l : Type Δ L) → (τ : Type Δ κ) → Type Δ R[ κ ]
151  _<$>_ : (φ : Type Δ (κ1 '→ κ2)) → (τ : Type Δ R[ κ1 ]) → Type Δ R[ κ2 ]
152  Π : {notLabel : True (notLabel? κ)} → Type Δ (R[ κ ] '→ κ)
153  Σ : {notLabel : True (notLabel? κ)} → Type Δ (R[ κ ] '→ κ)
154  _\ _ : Type Δ R[ κ ] → Type Δ R[ κ ] → Type Δ R[ κ ]
155

```

2.2.1 *The ordered predicate.* We impose on the $(|_)$ constructor a witness of the form `True (ordered? xs)`, although it may seem more intuitive to have instead simply required a witness that `Ordered xs`. The reason for this is that the `True` predicate quotients each proof down to a single inhabitant `tt`, which grants us proof irrelevance when comparing rows. This is desirable and yields congruence rules that would otherwise be blocked by two differing proofs of well-orderedness. The congruence rule below asserts that two simple rows are equivalent even with differing proofs. (This pattern is replicable for any decidable predicate.)

```

164  cong-SimpleRow : {sr1 sr2 : SimpleRow Type Δ R[ κ ]}
165                    {wf1 : True (ordered? sr1)} {wf2 : True (ordered? sr2)} →
166                    sr1 ≡ sr2 → (| sr1 |) wf1 ≡ (| sr2 |) wf2
167  cong-SimpleRow {sr1 = sr1} { } {wf1} {wf2} refl
168  rewrite Dec→Irrelevant (Ordered sr1) (ordered? sr1) wf1 wf2 = refl
169

```

In the same fashion, we impose on Π and Σ a similar restriction that their kinds satisfy the `NotLabel` predicate, although our reason for this restriction is instead metatheoretic: without it, nonsensical labels could be formed such as $\Pi \text{ (lab "a" } \triangleright \text{ lab "b")}$ or $\Pi \epsilon$. Each of these types have kind `L`, which violates a label canonicity theorem we later show that all label-kinded types in normal form are label literals or neutral.

2.2.2 *Flipped map operator.*

Hubers and Morris [2023] had a left- and right-mapping operator, but only one is necessary. The flipped application (`flap`) operator is defined below. Its type reveals its purpose.

```

180  flap : Type Δ (R[ κ1 '→ κ2 ] '→ κ1 '→ R[ κ2 ])
181  flap = 'λ ('λ (('λ (('Z) · (' (S Z)))) <$> (' (S Z))))
182
183  _??_ : Type Δ (R[ κ1 '→ κ2 ]) → Type Δ κ1 → Type Δ R[ κ2 ]
184  f ?? a = flap · f · a
185

```

2.2.3 *The (syntactic) complement operator.*

It is necessary to give a syntactic account of the computation incurred by the complement of two row literals so that we can state this computation later in the type equivalence relation. First, define a relation $\ell \in_L \rho$ that is inhabited when the label literal ℓ occurs in the row ρ . This relation is decidable ($_ \in_L ?_$, definition omitted).

```

192  data _∈L_ : (l : Label) → SimpleRow Type Δ R[ κ ] → Set where
193    Here : ∀ {τ : Type Δ κ} {xs : SimpleRow Type Δ R[ κ ]} {l : Label} →
194            l ∈L (l, τ) :: xs
195    There : ∀ {τ : Type Δ κ} {xs : SimpleRow Type Δ R[ κ ]} {l l' : Label} →
196

```

$l \in L \text{ } xs \rightarrow l \in L (l', \tau) :: xs$
 $_ \in L? _ : \forall (l : \text{Label}) (xs : \text{SimpleRow Type } \Delta \text{ } R[\kappa]) \rightarrow \text{Dec } (l \in L \text{ } xs)$

We now define the syntactic *row complement* effectively as a filter: when a label on the left is found in the row on the right, we exclude that labeled entry from the resulting row.

$_ \setminus s _ : \forall (xs \text{ } ys : \text{SimpleRow Type } \Delta \text{ } R[\kappa]) \rightarrow \text{SimpleRow Type } \Delta \text{ } R[\kappa]$
 $[] \setminus s \text{ } ys = []$
 $((l, \tau) :: xs) \setminus s \text{ } ys \text{ with } l \in L? \text{ } ys$
 $\dots \mid \text{yes } _ = xs \setminus s \text{ } ys$
 $\dots \mid \text{no } _ = (l, \tau) :: (xs \setminus s \text{ } ys)$

2.2.4 Type renaming and substitution.

A type variable renaming is a map from type variables in environment Δ_1 to type variables in environment Δ_2 .

$\text{Renaming}_k : \text{KEnv} \rightarrow \text{KEnv} \rightarrow \text{Set}$
 $\text{Renaming}_k \Delta_1 \Delta_2 = \forall \{\kappa\} \rightarrow \text{TVar } \Delta_1 \kappa \rightarrow \text{TVar } \Delta_2 \kappa$

This definition and approach is standard for the intrinsic style (cf. Chapman et al. [2019]; Wadler et al. [2022]) and so definitions are omitted. The only deviation of interest is that we have an obligation to show that renaming preserves the well-orderedness of simple rows. Note that we use the suffix $_k$ for common operations over the Type and Pred syntax; we will use the suffix $_k\text{NF}$ for equivalent operations over the normal type syntax.

$\text{orderedRenRow}_k : (r : \text{Renaming}_k \Delta_1 \Delta_2) \rightarrow (xs : \text{SimpleRow Type } \Delta_1 \text{ } R[\kappa]) \rightarrow \text{Ordered } xs \rightarrow \text{Ordered } (\text{renRow}_k \text{ } r \text{ } xs)$

A substitution is a map from type variables to types.

$\text{Substitution}_k : \text{KEnv} \rightarrow \text{KEnv} \rightarrow \text{Set}$
 $\text{Substitution}_k \Delta_1 \Delta_2 = \forall \{\kappa\} \rightarrow \text{TVar } \Delta_1 \kappa \rightarrow \text{Type } \Delta_2 \kappa$

Parallel renaming and substitution is likewise standard for this approach, and so definitions are omitted. As will become a theme, we must show that substitution preserves row well-orderedness.

$\text{orderedSubRow}_k : (\sigma : \text{Substitution}_k \Delta_1 \Delta_2) \rightarrow (xs : \text{SimpleRow Type } \Delta_1 \text{ } R[\kappa]) \rightarrow \text{Ordered } xs \rightarrow \text{Ordered } (\text{subRow}_k \text{ } \sigma \text{ } xs)$

Two operations of note: extension of a substitution σ appends a new type A as the zero'th De Bruijn index. β -substitution is a special case of substitution in which we only substitute the most recently freed variable.

$\text{extend}_k : \text{Substitution}_k \Delta_1 \Delta_2 \rightarrow (A : \text{Type } \Delta_2 \kappa) \rightarrow \text{Substitution}_k (\Delta_1 \text{ } \text{, } \kappa) \Delta_2$
 $\text{extend}_k \sigma \text{ } A \text{ } Z = A$
 $\text{extend}_k \sigma \text{ } A \text{ } (S \text{ } x) = \sigma \text{ } x$

$_ \beta_k _ : \text{Type } (\Delta \text{ } \text{, } \kappa_1) \kappa_2 \rightarrow \text{Type } \Delta \kappa_1 \rightarrow \text{Type } \Delta \kappa_2$
 $B \beta_k [A] = \text{sub}_k (\text{extend}_k \text{ } A) B$

2.3 Type equivalence

We define reduction on types $\tau \longrightarrow_{\mathcal{T}} \tau'$ by directing the following type equivalence judgment $\Delta \vdash \tau = \tau' : \kappa$ from left to right. We equate types under the relation $_ \equiv t _$, predicates under the relation $_ \equiv p _$, and row literals under the relation $_ \equiv r _$.

```
data _≡p_ : Pred Type Δ R[ κ ] → Pred Type Δ R[ κ ] → Set
data _≡t_ : Type Δ κ → Type Δ κ → Set
data _≡r_ : SimpleRow Type Δ R[ κ ] → SimpleRow Type Δ R[ κ ] → Set
```

Declare the following as generalized metavariables to reduce clutter. (N.b., generalized variables in Agda are not dependent upon each other, e.g., it is not true that ρ_1 and ρ_2 must have equal kinds when ρ_1 and ρ_2 appear in the same type signature.)

```
private
variable
  ℓ ℓ1 ℓ2 ℓ3 : Label
  l l1 l2 l3 : Type Δ L
  ρ1 ρ2 ρ3 : Type Δ R[ κ ]
  π1 π2 : Pred Type Δ R[ κ ]
  τ τ1 τ2 τ3 v v1 v2 v3 : Type Δ κ
```

Row literals and predicates are equated in an obvious fashion.

```
data _≡r_ where
  eq-[] : _≡r_ {Δ = Δ} {κ = κ} [] []
  eq-cons : {xs ys : SimpleRow Type Δ R[ κ ]} →
    ℓ1 ≡ ℓ2 → τ1 ≡t τ2 → xs ≡r ys →
    ((ℓ1, τ1) :: xs) ≡r ((ℓ2, τ2) :: ys)
```

```
data _≡p_ where
  _eq-≤_ : τ1 ≡t v1 → τ2 ≡t v2 → τ1 ≤ τ2 ≡p v1 ≤ v2
  _eq-·~_ : τ1 ≡t v1 → τ2 ≡t v2 → τ3 ≡t v3 →
    τ1 · τ2 ~ τ3 ≡p v1 · v2 ~ v3
```

The first three type equivalence rules enforce that $_ \equiv t _$ forms an equivalence relation.

```
data _≡t_ where
  eq-refl : τ ≡t τ
  eq-sym : τ1 ≡t τ2 → τ2 ≡t τ1
  eq-trans : τ1 ≡t τ2 → τ2 ≡t τ3 → τ1 ≡t τ3
```

We next have a number of congruence rules. As this is type-level normalization, we equate under binders such as λ and \forall . The rule for congruence under λ bindings is below; the remaining congruence rules are omitted.

```
eq-λ : ∀ {τ v : Type (Δ „ κ1) κ2} → τ ≡t v → ‘λ τ ≡t ‘λ v
```

We have two "expansion" rules and one composition rule. Firstly, arrow-kinded types are η -expanded to have an outermost lambda binding. This later ensures canonicity of arrow-kinded types.

eq- η : $\forall \{f : \text{Type} \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)\} \rightarrow f \equiv \lambda (\text{weaken}_k f \cdot (\cdot Z))$

Analogously, row-kinded variables left alone are expanded to a map by the identity function. Additionally, nested maps are composed together into one map. These rules together ensure canonical forms for row-kinded normal types. Observe that the last two rules are effectively functorial laws.

eq-map-id : $\forall \{\kappa\} \{\tau : \text{Type} \Delta R[\kappa]\} \rightarrow \tau \equiv \lambda \{\kappa_1 = \kappa\} (\cdot Z) <\$> \tau$
 eq-map- \circ : $\forall \{\kappa_3\} \{f : \text{Type} \Delta (\kappa_2 \xrightarrow{\quad} \kappa_3)\} \{g : \text{Type} \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)\} \{\tau : \text{Type} \Delta R[\kappa_1]\} \rightarrow$
 $(f <\$> (g <\$> \tau)) \equiv \lambda (\text{weaken}_k f \cdot (\text{weaken}_k g \cdot (\cdot Z))) <\$> \tau$

We now describe the computational rules that incur type reduction. Rule eq- β is the usual β -reduction rule. Rule eq-labTy asserts that the constructor $_ \triangleright _$ is indeed superfluous when describing singleton rows with a label literal; singleton rows of the form $(\ell \triangleright \tau)$ are normalized into row literals.

eq- β : $\forall \{\tau_1 : \text{Type} (\Delta _, \kappa_1) \kappa_2\} \{\tau_2 : \text{Type} \Delta \kappa_1\} \rightarrow$
 $((\lambda \tau_1) \cdot \tau_2) \equiv (\tau_1 \beta_k [\tau_2])$
 eq-labTy : $l \equiv \text{lab } \ell \rightarrow (l \triangleright \tau) \equiv \llbracket (\ell, \tau) \rrbracket \text{ tt}$

The rule eq- $\triangleright \$$ describes that mapping F over a singleton row is simply application of F over the row's contents. Rule eq-map asserts exactly the same except for row literals; the function over_r (definition omitted) is simply fmap over a pair's right component. Rule eq- $<\$> \setminus$ asserts that mapping F over a row complement is distributive.

eq- $\triangleright \$$: $\forall \{l\} \{\tau : \text{Type} \Delta \kappa_1\} \{F : \text{Type} \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)\} \rightarrow$
 $(F <\$> (l \triangleright \tau)) \equiv (l \triangleright (F \cdot \tau))$
 eq-map : $\forall \{F : \text{Type} \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)\} \{\rho : \text{SimpleRow Type} \Delta R[\kappa_1]\} \{\text{op} : \text{True} (\text{ordered? } \rho)\} \rightarrow$
 $F <\$> (\llbracket \rho \rrbracket \text{ op}) \equiv \llbracket \text{map} (\text{over}_r (F \cdot _)) \rho \rrbracket (\text{fromWitness} (\text{map-over}_r \rho (F \cdot _)) (\text{toWitness op}))$
 eq- $<\$> \setminus$: $\forall \{F : \text{Type} \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)\} \{\rho_2 \rho_1 : \text{Type} \Delta R[\kappa_1]\} \rightarrow$
 $F <\$> (\rho_2 \setminus \rho_1) \equiv (F <\$> \rho_2) \setminus (F <\$> \rho_1)$

The rules eq- Π and eq- Σ give the defining equations of Π and Σ at nested row kind. This is to say, application of Π to a nested row is equivalent to mapping Π over the row.

eq- Π : $\forall \{\rho : \text{Type} \Delta R[R[\kappa]]\} \{nl : \text{True} (\text{notLabel? } \kappa)\} \rightarrow$
 $\Pi \{notLabel = nl\} \cdot \rho \equiv \Pi \{notLabel = nl\} <\$> \rho$
 eq- Σ : $\forall \{\rho : \text{Type} \Delta R[R[\kappa]]\} \{nl : \text{True} (\text{notLabel? } \kappa)\} \rightarrow$
 $\Sigma \{notLabel = nl\} \cdot \rho \equiv \Sigma \{notLabel = nl\} <\$> \rho$

The next two rules assert that Π and Σ can reassociate from left-to-right except with the new right-applicand "flapped".

eq- Π -assoc : $\forall \{\rho : \text{Type} \Delta (R[\kappa_1 \xrightarrow{\quad} \kappa_2])\} \{\tau : \text{Type} \Delta \kappa_1\} \{nl : \text{True} (\text{notLabel? } \kappa_2)\} \rightarrow$
 $(\Pi \{notLabel = nl\} \cdot \rho) \cdot \tau \equiv \Pi \{notLabel = nl\} \cdot (\rho ?? \tau)$
 eq- Σ -assoc : $\forall \{\rho : \text{Type} \Delta (R[\kappa_1 \xrightarrow{\quad} \kappa_2])\} \{\tau : \text{Type} \Delta \kappa_1\} \{nl : \text{True} (\text{notLabel? } \kappa_2)\} \rightarrow$
 $(\Sigma \{notLabel = nl\} \cdot \rho) \cdot \tau \equiv \Sigma \{notLabel = nl\} \cdot (\rho ?? \tau)$

Finally, the rule eq-comp1 gives computational content to the relative row complement operator applied to row literals.

```

344 eq-compl : ∀ {xs ys : SimpleRow Type Δ R[ κ ]}
345   {oxs : True (ordered? xs)} {oys : True (ordered? ys)} {ozs : True (ordered? (xs \s ys))} →
346   (( xs ▷ oxs) \ (( ys ▷ oys) ≡t (( xs \s ys) ▷ ozs)
347

```

Before concluding, we share an auxiliary definition that reflects instances of propositional equality in Agda to proofs of type-equivalence. The same role could be performed via Agda's `subst` but without the convenience.

```

351 inst : ∀ {τ1 τ2 : Type Δ κ} → τ1 ≡ τ2 → τ1 ≡t τ2
352 inst refl = eq-refl
353

```

2.3.1 Some admissable rules. In early versions of this equivalence relation, we thought it would be necessary to impose the following two rules directly. However, we can confirm their admissability. The first rule states that Π is mapped over nested rows, and the second (definition omitted) states that λ -bindings η -expand over Π . (These results hold identically for Σ .)

```

359 eq-Π▷ : ∀ {l} {τ : Type Δ R[ κ ]} {nl : True (notLabel? κ)} →
360   (Π {notLabel = nl} · (l ▷ τ)) ≡t (l ▷ (Π {notLabel = nl} · τ))
361 eq-Π▷ = eq-trans eq-Π eq->$
362
363 eq-Πλ : ∀ {l} {τ : Type (Δ „ κ1) κ2} {nl : True (notLabel? κ2)} →
364   Π {notLabel = nl} · (l ▷ 'λ τ) ≡t 'λ (Π {notLabel = nl} · (weakenk l ▷ τ))
365

```

3 Normal forms

By directing the type equivalence relation we define computation on types. This serves as a sort of specification on the shape normal forms of types ought to have. Our grammar for normal types must be carefully crafted so as to be neither too "large" nor too "small". In particular, we wish our normalization algorithm to be *stable*, which implies surjectivity. Hence if the normal syntax is too large—i.e., it produces junk types—then these junk types will have pre-images in the domain of normalization. Inversely, if the normal syntax is too small, then there will be types whose normal forms cannot be expressed. Figure 2 specifies the syntax and typing of normal types, given as reference. We describe the syntax in more depth by describing its intrinsic mechanization.

	Type variables $\alpha \in \mathcal{A}$	Labels $\ell \in \mathcal{L}$
Ground Kinds	$\gamma ::= \star \mid L$	
Kinds	$\kappa ::= \gamma \mid \kappa \rightarrow \kappa \mid R^\kappa$	
Row Literals	$\hat{\mathcal{P}} \ni \hat{\rho} ::= \{\ell_i \triangleright \hat{\tau}_i\}_{i \in 0 \dots m}$	
Neutral Types	$n ::= \alpha \mid n \hat{\tau}$	
Normal Types	$\hat{\mathcal{T}} \ni \hat{\tau}, \hat{\phi} ::= n \mid \hat{\phi} \$ n \mid \hat{\rho} \mid \hat{\pi} \Rightarrow \hat{\tau} \mid \forall \alpha : \kappa. \hat{\tau} \mid \lambda \alpha : \kappa. \hat{\tau}$ $\mid n \triangleright \hat{\tau} \mid \ell \mid \# \hat{\tau} \mid \hat{\tau} \setminus \hat{\tau} \mid \Pi \hat{\tau} \mid \Sigma \hat{\tau}$	

Fig. 2. Normal type forms

3.1 Mechanized syntax

We define `NormalTypes` and `NormalPreds` analogously to `Types` and `Preds`. Recall that `Pred` and `SimpleRow` are indexed by the type of their contents, so we can reuse some code.

```

393 data NormalType (Δ : KEnv) : Kind → Set
394 NormalPred : KEnv → Kind → Set
395 NormalPred = Pred NormalType
396

```

We must declare an analogous orderedness predicate, this time for normal types. Its definition is nearly identical.

```

400 NormalOrdered : SimpleRow NormalType Δ R[ κ ] → Set
401 normalOrdered? : ∀ (xs : SimpleRow NormalType Δ R[ κ ]) → Dec (NormalOrdered xs)
402

```

Further, we define the predicate `NotSimpleRow` ρ to be true precisely when ρ is not a simple row. This is necessary because the row complement $\rho_2 \setminus \rho_1$ should reduce when each ρ_i is a row literal. So it is necessary when forming normal row-complements to specify that at least one of the complement operands is a non-literal. The predicate `True (notSimpleRows? ρ_1 ρ_2)` is satisfied precisely in this case.

```

409 NotSimpleRow : NormalType Δ R[ κ ] → Set
410 notSimpleRows? : ∀ (τ1 τ2 : NormalType Δ R[ κ ]) →
411     Dec (NotSimpleRow τ1 or NotSimpleRow τ2)
412

```

Neutral types are type variables and applications with type variables in head position.

```

415 data NeutralType Δ : Kind → Set where
416   ' : (α : TVar Δ κ) → NeutralType Δ κ
417   '·_ : (f : NeutralType Δ (κ1 '→ κ)) → (τ : NormalType Δ κ1) →
418       NeutralType Δ κ
419

```

We define the normal type syntax firstly by restricting the promotion of neutral types to normal forms at only *ground* kind. As discussed above, we restrict the formation of inert row complements to just those in which at least one operand is non-literal. We define inert maps as part of the `NormalType` syntax rather than the `NeutralType` syntax. Observe that a consequence of this decision (as opposed to letting the form `_<$>_` be neutral) is that all inert maps must have the mapped function composed into just one applicand. For example, the type $\phi_2 <$> (\phi_1 \text{ n})$ must recombine into $(\lambda \alpha. (\phi_2 (\phi_1 \alpha))) <$> \text{n}$ to be in normal form. Finally, we need only permit the formation of records and variants at kind \star , and we restrict the formation of neutral-labeled rows to just the singleton constructor `_▷n_`. The remaining cases are identical to the regular `Type` syntax and omitted.

```

431 data NormalType Δ where
432   ne : (x : NeutralType Δ κ) → {ground : True (ground? κ)} → NormalType Δ κ
433   _\_ : (ρ2 ρ1 : NormalType Δ R[ κ ]) → {nsr : True (notSimpleRows? ρ2 ρ1)} →
434       NormalType Δ R[ κ ]
435   _<$>_ : (φ : NormalType Δ (κ1 '→ κ2)) → NormalType Δ R[ κ1 ] → NormalType Δ R[ κ2 ]
436   Π : (ρ : NormalType Δ R[ ★ ]) → NormalType Δ ★
437   Σ : (ρ : NormalType Δ R[ ★ ]) → NormalType Δ ★
438   _▷n_ : (l : NeutralType Δ L) (τ : NormalType Δ κ) → NormalType Δ R[ κ ]
439

```

3.2 Canonicity of normal types

The syntax of normal types is defined precisely so as to enjoy canonical forms based on kind. We first demonstrate that neutral types and inert complements cannot occur in empty contexts.

$$\begin{array}{ll} \text{noNeutrals} : \text{NeutralType } \emptyset \kappa \rightarrow \perp & \text{noComplements} : \forall \\ \text{noNeutrals } (n \cdot \tau) = \text{noNeutrals } n & \{ \rho_1 \rho_2 \rho_3 : \text{NormalType } \emptyset R[\kappa] \} \\ & (nsr : \text{True } (\text{notSimpleRows? } \rho_3 \rho_2)) \rightarrow \\ & \rho_1 \equiv (\rho_3 \setminus \rho_2) \{nsr\} \rightarrow \\ & \perp \end{array}$$

Now, in any context an arrow-kinded type is canonically λ -bound:

$$\begin{array}{l} \text{arrow-canonicity} : (f : \text{NormalType } \Delta (\kappa_1 \xrightarrow{\quad} \kappa_2)) \rightarrow \exists [\tau] (f \equiv \lambda \tau) \\ \text{arrow-canonicity } (\lambda f) = f, \text{ refl} \end{array}$$

A row in an empty context is necessarily a row literal:

$$\begin{array}{l} \text{row-canonicity-}\emptyset : (\rho : \text{NormalType } \emptyset R[\kappa]) \rightarrow \\ \quad \exists [xs] \Sigma [oxs \in \text{True } (\text{normalOrdered? } xs)] \\ \quad (\rho \equiv \langle xs \rangle oxs) \\ \text{row-canonicity-}\emptyset (\langle \rho \rangle o\rho) = \rho, o\rho, \text{ refl} \end{array}$$

And a label-kinded type is necessarily a label literal:

$$\begin{array}{l} \text{label-canonicity-}\emptyset : \forall (l : \text{NormalType } \emptyset L) \rightarrow \exists [s] (l \equiv \text{lab } s) \\ \text{label-canonicity-}\emptyset (\text{ne } x) = \perp\text{-elim } (\text{noNeutrals } x) \\ \text{label-canonicity-}\emptyset (\text{lab } s) = s, \text{ refl} \end{array}$$

3.3 Renaming

Renaming over normal types is defined in an entirely straightforward manner. Types and definitions are omitted.

3.4 Embedding

The goal is to normalize a given $\tau : \text{Type } \Delta \kappa$ to a normal form at type $\text{NormalType } \Delta \kappa$. It is of course much easier to first describe the inverse embedding, which recasts a normal form back to its original type. Definitions are expected and omitted.

$$\begin{array}{l} \uparrow : \text{NormalType } \Delta \kappa \rightarrow \text{Type } \Delta \kappa \\ \uparrow\text{Row} : \text{SimpleRow NormalType } \Delta R[\kappa] \rightarrow \text{SimpleRow Type } \Delta R[\kappa] \\ \uparrow\text{NE} : \text{NeutralType } \Delta \kappa \rightarrow \text{Type } \Delta \kappa \\ \uparrow\text{Pred} : \text{NormalPred } \Delta R[\kappa] \rightarrow \text{Pred Type } \Delta R[\kappa] \end{array}$$

Note that it is precisely in "embedding" the `NormalOrdered` predicate that we establish half of the requisite isomorphism between a normal row being normal-ordered and its embedding being ordered. We will have to show the other half (that is, that ordered rows have normal-ordered evaluations) during normalization.

$$\begin{array}{l} \text{Ordered}\uparrow : \forall (\rho : \text{SimpleRow NormalType } \Delta R[\kappa]) \rightarrow \text{NormalOrdered } \rho \rightarrow \\ \quad \text{Ordered } (\uparrow\text{Row } \rho) \end{array}$$

4 Semantic types

We have finally set the stage to discuss the process of normalizing types by evaluation. We first must define a semantic image of Types into which we will evaluate. Crucially, neutral types must *reflect* into this domain, and elements of this domain must *reify* to normal forms.

Let us first define the image of row literals to be Fin -indexed maps.

$\text{Row} : \text{Set} \rightarrow \text{Set}$

$\text{Row } A = \exists [n] (\text{Fin } n \rightarrow \text{Label} \times A)$

Naturally, we required a predicate on such rows to indicate that they are well-ordered.

$\text{OrderedRow}' : \forall \{A : \text{Set}\} \rightarrow (n : \mathbb{N}) \rightarrow (\text{Fin } n \rightarrow \text{Label} \times A) \rightarrow \text{Set}$

$\text{OrderedRow}' \text{ zero } P = \top$

$\text{OrderedRow}' (\text{suc zero}) P = \top$

$\text{OrderedRow}' (\text{suc} (\text{suc } n)) P = (P \text{ fzero} .\text{fst} < P (\text{fsuc fzero}) .\text{fst}) \times \text{OrderedRow}' (\text{suc } n) (P \circ \text{fsuc})$

$\text{OrderedRow} : \forall \{A\} \rightarrow \text{Row } A \rightarrow \text{Set}$

$\text{OrderedRow } (n, P) = \text{OrderedRow}' n P$

We may now define the totality of forms a row-kinded type might take in the semantic domain (the RowType data type). We evaluate row literals into Rows via the row constructor; note that the argument \mathcal{T} maps kinding environments to types. In practice, this is how we specify that a row contains types in environment Δ .

$\text{data RowType } (\Delta : \text{KEnv}) (\mathcal{T} : \text{KEnv} \rightarrow \text{Set}) : \text{Kind} \rightarrow \text{Set}$

$\text{NotRow} : \forall \{\Delta : \text{KEnv}\} \{\mathcal{T} : \text{KEnv} \rightarrow \text{Set}\} \rightarrow \text{RowType } \Delta \mathcal{T} R[\kappa] \rightarrow \text{Set}$

$\text{data RowType } \Delta \mathcal{T} \text{ where}$

$\text{row} : (\rho : \text{Row } (\mathcal{T} \Delta)) \rightarrow \text{OrderedRow } \rho \rightarrow \text{RowType } \Delta \mathcal{T} R[\kappa]$

$_ \triangleright _ : \text{NeutralType } \Delta L \rightarrow \mathcal{T} \Delta \rightarrow \text{RowType } \Delta \mathcal{T} R[\kappa]$

$_ \setminus _ : (\rho_2 \rho_1 : \text{RowType } \Delta \mathcal{T} R[\kappa]) \rightarrow \{nr : \text{NotRow } \rho_2 \text{ or NotRow } \rho_1\} \rightarrow \text{RowType } \Delta \mathcal{T} R[\kappa]$

$_ \text{<\$> } _ : (\phi : \forall \{\Delta'\} \rightarrow \text{Renaming}_k \Delta \Delta' \rightarrow \text{NeutralType } \Delta' \kappa_1 \rightarrow \mathcal{T} \Delta') \rightarrow$

$\text{NeutralType } \Delta R[\kappa_1] \rightarrow$

$\text{RowType } \Delta \mathcal{T} R[\kappa_2]$

Neutral-labeled singleton rows are evaluated into the $_ \triangleright _$ constructor; inert complements are evaluated into the $_ \setminus _$ constructor. Just as OrderedRow is the semantic version of row well-orderedness, the predicate NotRow asserts that a given RowType is not a row literal (constructed by row). This ensures that complements constructed by $_ \setminus _$ are indeed inert. Regarding the inert map constructor, we would like to compose nested maps. Borrowing from Allais et al. [2013], we thus interpret the left applicand of a map as a Kripke function space mapping neutral types in environment Δ' to the type $\mathcal{T} \Delta'$, which we will later specify to be that of semantic types in environment Δ' at kind κ . To avoid running afoul of Agda's positivity checker, we let the domain type of this Kripke function be *neutral types*, which may always be reflected into semantic types. We define semantic types (SemType) below, but replacing $\text{NeutralType } \Delta' \kappa_1$ with $\text{SemType } \Delta' \kappa_1$ would not be strictly positive.

We finally define the semantic domain by induction on the kind κ . Types with \star and label kind are simply NormalTypes . We interpret functions into *Kripke function spaces*—that is, functions

that operate over `SemType` inputs at any possible environment Δ_2 , provided a renaming into Δ_2 . We interpret row-kinded types into the `RowType` type, defined above. Note some more trickery which we have borrowed from Allais et al. [2013]: we cannot pass `SemType` itself as an argument to `RowType` (which would violate termination checking), but we can instead pass to `RowType` the function $(\lambda \Delta' \rightarrow \text{SemType } \Delta' \kappa)$, which enforces a strictly smaller recursive call on the kind κ . Observe too that abstraction over the kinding environment Δ' is necessary because our representation of inert maps `<$>` interprets the mapped applicand as a Kripke function space over neutral type

```
SemType : KEnv → Kind → Set
SemType Δ ★ = NormalType Δ ★
SemType Δ L = NormalType Δ L
SemType Δ1 (κ1 '→ κ2) = (∀ {Δ2} → (r : Renamingk Δ1 Δ2)
    (v : SemType Δ2 κ1) → SemType Δ2 κ2)
SemType Δ R[κ] = RowType Δ (λ Δ' → SemType Δ' κ) R[κ]
```

For abbreviation later, we alias our two types of Kripke function spaces as so:

```
KripkeFunction : KEnv → Kind → Kind → Set
KripkeFunction Δ1 κ1 κ2 =
  (∀ {Δ2} → Renamingk Δ1 Δ2 →
    SemType Δ2 κ1 → SemType Δ2 κ2)

KripkeFunctionNE : KEnv → Kind → Kind → Set
KripkeFunctionNE Δ1 κ1 κ2 =
  (∀ {Δ2} → Renamingk Δ1 Δ2 →
    NeutralType Δ2 κ1 → SemType Δ2 κ2)
```

4.1 Renaming

Renaming a Kripke function is nothing more than providing the appropriate renaming to the function.

```
renSem : Renamingk Δ1 Δ2 → SemType Δ1 κ → SemType Δ2 κ
renKripke : Renamingk Δ1 Δ2 → KripkeFunction Δ1 κ1 κ2 → KripkeFunction Δ2 κ1 κ2
renKripke {Δ1} ρ F {Δ2} = λ ρ' → F (ρ' ∘ ρ)
```

Renaming a row is simply pre-composition of the renaming r over the row's map P . The helper `overr` lifts `renSem r` over the tuple, applying `renSem r` to the second component.

```
renRow : Renamingk Δ1 Δ2 → Row (SemType Δ1 κ) → Row (SemType Δ2 κ)
renRow r (n , P) = n , overr (renSem r) ∘ P
```

Renaming over semantic types is otherwise defined in a straightforward manner. At kinds \star and L , we defer to the renaming of normal types. The other cases are described above or simply compositional. Some care must be given to ensure that the `NotRow` and well-ordered predicates are preserved. (We omit the auxiliary lemmas `orderedRenRow` and `nrRenSem'`.)

```
renSem {κ = ★} r τ = renkNF r τ
renSem {κ = L} r τ = renkNF r τ
renSem {κ = κ' '→ κ1} r F = renKripke r F
renSem {κ = R[κ]} r (φ <$> x) = (λ r' → φ (r' ∘ r)) <$> (renkNE r x)
renSem {κ = R[κ]} r (row (n , P) q) = row (renRow r (n , P)) (orderedRenRow r q)
renSem {κ = R[κ]} r (l ▷ τ) = (renkNE r l) ▷ renSem r τ
renSem {κ = R[κ]} r ((ρ2 \ ρ1) {nr}) = (renSem r ρ2 \ renSem r ρ1) {nr = nrRenSem' r ρ2 ρ1 nr}
```

5 Normalization by Evaluation (NbE)

We have now declared three domains: the syntax of types, the syntax of normal and neutral types, and the embedded domain of semantic types. Normalization by evaluation (NbE), as we follow it, involves producing a *reflection* from neutral types to semantic types, a *reification* from semantic types to normal types, and an *evaluation* from types to semantic types. It follows thereafter that normalization is the reification of evaluation. Because we reason about types modulo η -expansion, reflection and reification are necessarily mutually recursive. (This is not the case however with e.g. Chapman et al. [2019].)

We describe the reflection logic before reification. Types at kind \star and L can be promoted straightforwardly with the `ne` constructor. A neutral row (e.g., a row variable) must be expanded into an inert mapping by $(\lambda r \ n \rightarrow \text{reflect } n)$, which is effectively the identity function. Finally, neutral types at arrow kind must be expanded into Kripke functions. Note that the input v has type $\text{SemType } \Delta \ \kappa_1$ and must be reified.

```

reflect :  $\forall \{ \kappa \} \rightarrow \text{NeutralType } \Delta \ \kappa \rightarrow \text{SemType } \Delta \ \kappa$ 
reify   :  $\forall \{ \kappa \} \rightarrow \text{SemType } \Delta \ \kappa \rightarrow \text{NormalType } \Delta \ \kappa$ 

reflect { $\kappa = \star$ }  $\tau$       = ne  $\tau$ 
reflect { $\kappa = L$ }  $\tau$       = ne  $\tau$ 
reflect { $\kappa = R[ \ \kappa \ ]$ }  $\rho = (\lambda r \ n \rightarrow \text{reflect } n) <\$> \rho$ 
reflect { $\kappa = \kappa_1 \rightarrow \kappa_2$ }  $\tau = \lambda \rho \ v \rightarrow \text{reflect } (\text{ren}_k \text{NE } \rho \ \tau \cdot \text{reify } v)$ 
```

Stopping here.

5.4 Normalization

$\Downarrow : \forall \{\Delta\} \rightarrow \text{Type } \Delta \kappa \rightarrow \text{NormalType } \Delta \kappa$
 $\Downarrow \tau = \text{reify } (\text{eval } \tau \text{ idEnv})$
 $\Downarrow \text{Pred} : \forall \{\Delta\} \rightarrow \text{Pred Type } \Delta \text{R}[\kappa] \rightarrow \text{Pred NormalType } \Delta \text{R}[\kappa]$
 $\Downarrow \text{Pred } \pi = \text{evalPred } \pi \text{ idEnv}$
 $\Downarrow \text{Row} : \forall \{\Delta\} \rightarrow \text{SimpleRow Type } \Delta \text{R}[\kappa] \rightarrow \text{SimpleRow NormalType } \Delta \text{R}[\kappa]$
 $\Downarrow \text{Row } \rho = \text{reifyRow } (\text{evalRow } \rho \text{ idEnv})$
 $\Downarrow \text{NE} : \forall \{\Delta\} \rightarrow \text{NeutralType } \Delta \kappa \rightarrow \text{NormalType } \Delta \kappa$
 $\Downarrow \text{NE } \tau = \text{reify } (\text{eval } (\Downarrow \text{NE } \tau) \text{ idEnv})$

6 Metatheory

6.1 Stability

$\text{stability} : \forall (\tau : \text{NormalType } \Delta \kappa) \rightarrow \Downarrow (\Uparrow \tau) \equiv \tau$
 $\text{stabilityNE} : \forall (\tau : \text{NeutralType } \Delta \kappa) \rightarrow \text{eval } (\Uparrow \text{NE } \tau) (\text{idEnv } \{\Delta\}) \equiv \text{reflect } \tau$
 $\text{stabilityPred} : \forall (\pi : \text{NormalPred } \Delta \text{R}[\kappa]) \rightarrow \text{evalPred } (\Uparrow \text{Pred } \pi) \text{ idEnv} \equiv \pi$
 $\text{stabilityRow} : \forall (\rho : \text{SimpleRow NormalType } \Delta \text{R}[\kappa]) \rightarrow \text{reifyRow } (\text{evalRow } (\Uparrow \text{Row } \rho) \text{ idEnv}) \equiv \rho$

Stability implies surjectivity and idempotency.

$\text{idempotency} : \forall (\tau : \text{Type } \Delta \kappa) \rightarrow (\Uparrow \circ \Downarrow \circ \Uparrow \circ \Downarrow) \tau \equiv (\Uparrow \circ \Downarrow) \tau$
 $\text{idempotency } \tau \text{ rewrite stability } (\Downarrow \tau) = \text{refl}$
 $\text{surjectivity} : \forall (\tau : \text{NormalType } \Delta \kappa) \rightarrow \exists [v] (\Downarrow v \equiv \tau)$
 $\text{surjectivity } \tau = (\Uparrow \tau, \text{stability } \tau)$

Dual to surjectivity, stability also implies that embedding is injective.

$\Uparrow\text{-inj} : \forall (\tau_1 \tau_2 : \text{NormalType } \Delta \kappa) \rightarrow \Uparrow \tau_1 \equiv \Uparrow \tau_2 \rightarrow \tau_1 \equiv \tau_2$
 $\Uparrow\text{-inj } \tau_1 \tau_2 \text{ eq} = \text{trans } (\text{sym } (\text{stability } \tau_1)) (\text{trans } (\text{cong } \Downarrow \text{ eq}) (\text{stability } \tau_2))$

6.2 A logical relation for completeness

6.5 The fundamental theorem and soundness

```

fundS :  $\forall \{\Delta_1 \Delta_2 \kappa\}(\tau : \text{Type } \Delta_1 \kappa)\{\sigma : \text{Substitution}_k \Delta_1 \Delta_2\}\{\eta : \text{Env } \Delta_1 \Delta_2\} \rightarrow$ 
   $\llbracket \sigma \rrbracket \approx_e \eta \rightarrow \llbracket \text{sub}_k \sigma \tau \rrbracket \approx (\text{eval } \tau \eta)$ 
fundSRow :  $\forall \{\Delta_1 \Delta_2 \kappa\}(xs : \text{SimpleRow Type } \Delta_1 \text{ R } [\kappa])\{\sigma : \text{Substitution}_k \Delta_1 \Delta_2\}\{\eta : \text{Env } \Delta_1 \Delta_2\} \rightarrow$ 
   $\llbracket \sigma \rrbracket \approx_e \eta \rightarrow \llbracket \text{subRow}_k \sigma xs \rrbracket r \approx (\text{evalRow } xs \eta)$ 
fundSPred :  $\forall \{\Delta_1 \kappa\}(\pi : \text{Pred Type } \Delta_1 \text{ R } [\kappa])\{\sigma : \text{Substitution}_k \Delta_1 \Delta_2\}\{\eta : \text{Env } \Delta_1 \Delta_2\} \rightarrow$ 
   $\llbracket \sigma \rrbracket \approx_e \eta \rightarrow (\text{subPred}_k \sigma \pi) \equiv_p \uparrow \text{Pred } (\text{evalPred } \pi \eta)$ 

```

– Fundamental theorem when substitution is the identity

```

subk-id :  $\forall (\tau : \text{Type } \Delta \kappa) \rightarrow \text{sub}_k \tau \equiv \tau$ 
 $\vdash \llbracket \tau \rrbracket \approx \vdash (\tau : \text{Type } \Delta \kappa) \rightarrow \llbracket \tau \rrbracket \approx \text{eval } \tau \text{ idEnv}$ 
 $\vdash \llbracket \tau \rrbracket \approx \text{subst-}\llbracket \tau \rrbracket \approx (\text{inst } (\text{sub}_k\text{-id } \tau)) (\text{fundS } \tau \text{ idSR})$ 

```

– Soundness claim

```

soundness :  $\forall \{\Delta_1 \kappa\} \rightarrow (\tau : \text{Type } \Delta_1 \kappa) \rightarrow \tau \equiv_t \uparrow \downarrow \tau$ 
soundness  $\tau = \text{reify-}\llbracket \tau \rrbracket \approx (\vdash \llbracket \tau \rrbracket \approx)$ 

```

– If τ_1 normalizes to $\downarrow \tau_2$ then the embedding of τ_1 is equivalent to τ_2

```

embed- $\equiv_t$  :  $\forall \{\tau_1 : \text{NormalType } \Delta \kappa\} \{\tau_2 : \text{Type } \Delta \kappa\} \rightarrow \tau_1 \equiv (\downarrow \tau_2) \rightarrow \uparrow \tau_1 \equiv_t \tau_2$ 
embed- $\equiv_t$   $\{\tau_1 = \tau_1\} \{\tau_2\} \text{ refl} = \text{eq-sym } (\text{soundness } \tau_2)$ 

```

– Soundness implies the converse of completeness, as desired

```

Completeness-1 :  $\forall \{\Delta \kappa\} \rightarrow (\tau_1 \tau_2 : \text{Type } \Delta \kappa) \rightarrow \downarrow \tau_1 \equiv \downarrow \tau_2 \rightarrow \tau_1 \equiv_t \tau_2$ 
Completeness-1  $\tau_1 \tau_2 \text{ eq} = \text{eq-trans } (\text{soundness } \tau_1) (\text{embed-}\equiv_t \text{ eq})$ 

```

7 The rest of the picture

In the remainder of the development, we intrinsically represent terms as typing judgments indexed by normal types. We then give a typed reduction relation on terms and show progress.
